§1 Introduction to Deep Learning in Python

§1.1 Basics of deep learning and neural networks

1 Activation functions

1.1 How do activation functions work?

It is applied to node inputs to produce node output.

1.2 What is the rectified linear activation (ReLU)?

$$RELU(x) = \begin{cases} 0 & \text{if } x < 0 \\ x & \text{if } x \geq 0 \end{cases}$$

1.3 Code of activation functions:

```
[1]: import numpy as np

input_data = np.array([-1, 2])
weights = {
    'node_0': np.array([3, 3]),
    'node_1': np.array([1, 5]),
    'output': np.array([2, -1])
}
node_0_input = (input_data * weights['node_0']).sum()
node_0_output = np.tanh(node_0_input)
node_1_input = (input_data * weights['node_1']).sum()
node_1_output = np.tanh(node_1_input)
hidden_layer_outputs = np.array([node_0_output, node_1_output])
output = (hidden_layer_outputs * weights['output']).sum()

print(output)
```

0.9901095378334199

1.4 Practice exercises for activation functions:

► Package pre-loading:

```
[2]: import numpy as np
```

► Data pre-loading:

```
[3]: input_data = np.array([3, 5])

weights = {
```

```
'node_0': np.array([2, 4]),  
'node_1': np.array([4, -5]),  
'output': np.array([2, 7])  
}
```

► The rectified linear activation function practice:

```
[4]: def relu(input):  
    '''Define your relu activation function here'''  
    # Calculate the value for the output of the relu function: output  
    output = max(0, input)  
  
    # Return the value just calculated  
    return (output)  
  
    # Calculate node 0 value: node_0_output  
    node_0_input = (input_data * weights['node_0']).sum()  
    node_0_output = relu(node_0_input)  
  
    # Calculate node 1 value: node_1_output  
    node_1_input = (input_data * weights['node_1']).sum()  
    node_1_output = relu(node_1_input)  
  
    # Put node values into array: hidden_layer_outputs  
    hidden_layer_outputs = np.array([node_0_output, node_1_output])  
  
    # Calculate model output (do not apply relu)  
    model_output = (hidden_layer_outputs * weights['output']).sum()  
  
    # Print model output  
    print(model_output)
```

52

► Data re-pre-loading:

```
[5]: input_data = [  
    np.array([3, 5]),  
    np.array([1, -1]),  
    np.array([0, 0]),  
    np.array([8, 4])  
]
```

► Network to many observations/rows of data applying practice:

```
[6]: # Define predict_with_network()  
def predict_with_network(input_data_row, weights):
```

```
# Calculate node 0 value
node_0_input = (input_data_row * weights['node_0']).sum()
node_0_output = relu(node_0_input)

# Calculate node 1 value
node_1_input = (input_data_row * weights['node_1']).sum()
node_1_output = relu(node_1_input)

# Put node values into array: hidden_layer_outputs
hidden_layer_outputs = np.array([node_0_output, node_1_output])

# Calculate model output
input_to_final_layer = (hidden_layer_outputs * weights['output']).sum()
model_output = relu(input_to_final_layer)

# Return model output
return (model_output)

# Create empty list to store prediction results
results = []
for input_data_row in input_data:
    # Append prediction to results
    results.append(predict_with_network(input_data_row, weights))

# Print results
print(results)
```
